The Emotional Impact of Dating Apps for LGBTQ+ Users

Sayoojya Jayan, Jayden Kang, Selah Key, Nicolas Rodriguez, Evelyn Tran

HCDE 519 Sp 2026

1 Executive Summary

Dating apps are a primary channel for romantic connection among LGBTQ+ young adults, yet research on their emotional impact has largely viewed these platforms through a heterosexual lens or focused only on extreme cases of harassment. This study examined the everyday emotional dynamics of dating app use for LGBTQ+ young adults: how design shapes what users feel, how those feelings affect self-perception, and how users make sense of their experiences.

We conducted a 7-day voice diary study followed by semi-structured interviews with four LGBTQ+ young adults who were active users of swipe-based dating apps. Diary entries captured in-the-moment emotional reactions before recall could fade, and interviews probed the motivations and contexts behind them. Transcripts were analyzed through inductive thematic coding and affinity diagramming.

Our analysis resulted in several important findings. Current dating apps are not designed to foster deep interpersonal connection, which contradicts users' motivations and directly harms their emotions at every stage, from people discovery to sustaining conversations. Participants joined the apps to build genuine, identity-aligned relationships and evaluated potential partners primarily by personality, but encountered a visual-centric architecture in which photos carried nearly all decision-making weight. Profiles were a medium to express their identities, orientations, and personality, all connected to their sense of safety. Yet the photo-first design failed them at both ends. Other users' photo-only attention dismissed the identities and boundaries they had disclosed, and the medium itself lacked the in-depth personal cues needed to judge whether someone was a safe, personality-compatible person at all. Over time, the uncertainty the apps produced turned inward as self-doubt about social skill, desirability, and standards, accumulating into emotional fatigue, lowered expectations, and guarded re-engagement.

These findings call on designers to give personality structural weight rather than optimizing for visual-centric engagement, and offer LGBTQ+ users validation that draining app experiences reflect design, not personal failure.

2 Motivation and Background

Dating is fundamentally different in the era of apps, and numbers of research document the cost. People who use dating apps report higher levels of depression, anxiety, and loneliness compared to non-users, and over time many experience dating app burnout, an emotional exhaustion that erodes the motivation to form meaningful connections (Sharbini et al., 2025). Much of this harm appears to be structural. Swipe-based interactions borrow the variable reward mechanics of slot machines, hooking users into compulsive engagement rather than connection (Sharbini et al., 2025). Choice overload produces decision fatigue (New Media & Society, 2023), boredom-driven use predicts lower satisfaction and emotional volatility (Bai, 2023), and the platforms' visual

nature is linked to body dissatisfaction and lowered self-esteem (Bowman et al., 2024). Dating apps shape not only how people meet, but how they feel.

Yet dating apps are arguably more consequential for LGBTQ+ users than for any other group. Smaller dating pools, fewer physical safe spaces to meet, and the safety risks attached to public disclosure of queer identity make digital platforms a primary, sometimes only, channel for romantic connection. Despite this, most existing research views dating apps through a heterosexual lens, and when studies do center queer users, they tend to focus on extreme cases of safety and harassment, such as harm on platforms like Grindr. Far less attention has been paid to the everyday emotional dynamics of app use: how users feel after browsing profiles, sending a message that goes unanswered, or receiving a like from someone who never read their profile. These small, repeated interactions are precisely where design decisions and well-being meet, yet their emotional weight is not well documented for queer populations.

Our motivation is to address this gap. We sought to understand the specific emotional mechanisms through which app design produces these everyday experiences, and how users' own motivations shape what the same interactions come to mean. By documenting these mechanisms, we aim to give designers evidence for building digital ecosystems that prioritize genuine connection over endless engagement.

This study uses phenomenological HCI as its theoretical base. Following Dourish (2001), we view users as meaning-making agents whose experience of technology is inseparable from their social world and sense of self. To understand why a user feels a certain way after opening an app, we must look beyond the screen to what the user brought to the interaction and how their communities help them process it. This perspective shaped our analytical approach, while we guarded against confirmation bias by generating insights inductively from the data.

3 Research Questions

Our team focused on the following research questions:

1. What motivations and expectations do LGBTQ+ young adults have when joining dating apps?
2. How do different interactions within dating apps affect an LGBTQ+ young adult's self-perception and emotional well-being?
3. What external factors play into their sensemaking of their experiences?

These questions are designed to holistically examine the impact of dating app engagement on digital well-being across three dimensions. By questioning motivations and expectations (RQ1), the study establishes a baseline of user intent. Focusing on interactions, self-perception, and emotional well-being (RQ2) creates space to investigate the psychological impact of digital

interactions. Finally, analyzing external factors in sensemaking (RQ3) situates these experiences in a broader social and personal context.

Grounded in the phenomenological HCI perspective (Dourish, 2001), which holds that users create meaning through lived experience and interaction with technology, these questions form a funnel: from the abstract (expectations), to the visceral (self-perception and emotion), and finally to the contextual (sensemaking).

4 Methods

For this study we selected a 7-day diary study paired with a post-study semi-structured interview. This pairing of methods was chosen because dating app interactions are characteristically brief and emotionally subtle, which makes retrospective recall unreliable as a primary data source. We want to be able to explore the specific emotional reactions of those micro-moments that could fade by the time an interview with a researcher is scheduled.

The diary study addressed this by capturing participants' unfiltered, in-the-moment responses after using a dating app of their choice. Voice journaling was chosen over text journaling specifically because audio preserves emotional tone, hesitation, and spontaneous reflection in ways that written responses can not achieve. Participants submitted audio files of at least one minute per day via Google Form in response to three prompts: how they felt while using the app that day and what happened, were there any memorable interactions or moments, and how did they feel about themselves after using the dating apps.

The post-study interview provided contextual depth that diary entries alone could not provide. While the diaries captured the raw 'what' the interviews allowed us to probe the 'why' including participants' foundational motivations for using the apps, the prior experiences shaping their interpretations, and the social contexts through which they made sense of their feelings. Interviews were conducted via Zoom, lasted approximately 40 minutes, and followed a semi-structured guide that included diary-based probes tied to specific moments from each participant's own recordings.

4.1 Participants

We recruited LGBTQ+ young adults between the ages of 18 and 29 who were active users of mainstream swipe-based dating applications, defined as having engaged with at least one app at least once per week during their most recent period of active use. Participants' most recent usage must have occurred within the past three months, ensuring that their experiences reflected the current app landscape and algorithmic environment. We targeted four to eight participants, through the use of a participant screener we were able to recruit four people to be part of the study. A full participant pool table can be found in the appendix (*9.1.3 Participant Pool Table*)

Participant 4 (P4) completed the full 7-day diary study but chose to withdraw before the post-study interview. This decision was fully respected. P4's diary data was retained in analysis,

though interpreted with appropriate caution given the absence of interview depth for that participant.

4.2 Recruitment Procedures

Recruitment was conducted by distributing a screening survey via Slack workspaces, social media platforms, and the personal networks of the research team. The survey collected demographic information, dating app usage history, and willingness to participate in a week-long study. Participants were not offered compensation. The screening criteria prioritized active, recent dating app experience rather than specific app identity, allowing participants to report on whichever platforms they used, including Tinder, Hinge, Bumble, and Grindr.

4.3 Data Analysis

Analysis proceeded in three stages. First, all audio diary entries and interview recordings were transcribed in full and anonymized, with participant names replaced by coded identifiers.

Second, we conducted inductive thematic coding of the transcripts. This approach generated codes from the data itself rather than from a pre-existing set, ensuring that our categories emerged from participants' actual language and experience. Each code represented a micro-level observation across one or more participants, labeled with a domain prefix (MT for motivation, IN for interaction, FN for feeling negative, BH for behavior, PO for perception outward, PI for perception inward) and a description. Codes were paired with supporting excerpts from both diary and interview data. Two team members coded each participant’s data so the data was not interpreted by one person. The full codebook is provided in the appendix *(9.3.5 Codebook)*.

Third, we moved codes into an affinity diagram, grouping micro-level codes into higher-order thematic clusters through collaborative team review. This process revealed the relational and temporal structure of the findings, specifically the progression from motivation through interaction to emotional fatigue to behavioral response, which became the organizational logic of our key finding. The affinity diagrams are referenced in the appendix *(9.3.2 Diary Study Coding Affinity Mapping and 9.3.4 Interview Coding Affinity Mapping)*.

4.4 Ethical Considerations

Given the sensitivity of topics including LGBTQ+ identity, dating, mental health, and self-perception, ethical considerations were foundational to the study's design. All participants provided informed consent after receiving a full explanation of the study's goals, procedures, and potential emotional risks. Participation was explicitly voluntary, participants could skip any question or withdraw at any time without penalty, as P4 did. Data was accessible only to the research team, and all published quotes and insights were fully anonymized. Throughout all contact with participants, we maintained a non-judgmental, affirming tone and explicitly acknowledged the potential for emotional discomfort associated with the study's subject matter.

5 Findings

Our analysis surfaced one overarching finding that cuts across all three research questions: current dating apps are not designed to foster deep interpersonal connection. Participants entered the apps with a personality-first standard for relationships and encountered an architecture built around photos. The friction between the two shaped their perceptions, emotions, and behaviors at every stage of engagement, and its weight was amplified by their LGBTQ+ identities, for whom profile information is not only a compatibility signal but a safety signal. The findings below follow this arc: how motivations formed, how the visual-centric structure collided with those motivations, how that collision registered emotionally and turned inward as self-doubt, how participants coped, and how repeated cycles produced fatigue and reshaped their motivation.

5.1 Motivation: Building Genuine, Identity-Aligned Relationships Outside Existing Social Circles

Across all four participants, interviews and diary entries revealed a shared initial motivation: to build genuine relationships aligned with their sexual identity, and to explore people outside their existing social circles in order to achieve that. This motivation was assembled from three interacting sources. First, participants' self-perception included an awareness that finding identity-aligned people is structurally difficult. Second, pre-formed knowledge framed the apps as a reasonable bet. Social success stories circulated around them, and the apps appeared to be a low-risk way to expand romantic options beyond who they already knew. Third, external triggers converted latent interest into action. Friends' recommendations, offered after a breakup or in casual social settings, were the moments that led to actual downloads.

All participants also shared the same core priority in evaluating potential partners, personality. This standard was shaped by their previous relationships and life experiences. As P3 put it, "every single crush I've ever had has been something to do with their personality... after I've had a deep conversation with them or an emotional connection with them." P1 stated the same priority plainly, tending "to value a person's personality over anything else," and P2 framed it as wanting evidence of an inner life: "I want to know that if I'm going to go on a date with somebody that they are passionate about something... they have actual stuff going on in their lives."

This motivation and these core values shaped everything that followed. They determined how participants perceived the interactions and triggers the apps presented to them, and they drove the coping behaviors participants developed during engagement. The remaining findings trace both threads.

5.2 Mismatch Between Personality-First Values and the Platform's Visual-Centric Architecture

Once starting the engagement on apps, participants experienced a profound friction between their core relationship priority, personality, and the platform's structural architecture.

5.2.1 What participants meant by "visual-centric"

Participants repeatedly characterized the apps as visual-centric, and their accounts let us specify what this meant. It referred to three reinforcing layers. The first is architectural. The photo is the main medium through which a person exists on the app. The interface is designed so that users browse people by photo at first glance and only afterward, optionally, open the detailed profile. The second layer is content. Because photos carry the burden of introduction to an unknown majority, the photos that circulate showcase toned bodies, abs, faces, and occasionally travel, lifestyle, or markers of wealth, with very little clue about who the person actually is. P2 described the most common profile type as people "pretending to be super successful," filled with vacation pictures and career claims: "cool, that's great that you have a good career and stuff, but that doesn't tell me anything about you as a person." P3 summarized the resulting deficit as a need the interface could not meet: "There's nothing compelling besides the pictures... I need some more perspective, I just need some more depth, maybe I just need more information." The third layer is behavioral, and we return to it in 4.2.3: an interface that rewards photo-first evaluation trains users to interact through photos alone.

5.2.2 What the photo medium strips out: communication as context and safety

The depth participants missed was not an abstract preference. It reflected a richer definition of communication that the apps could not transmit. P3 defined communication expansively as "exchanging any information, even if through silence," including the nod exchanged with a stranger on the street, unintended eye contact, a wink, a wave, or "even just sitting still existing in silence" beside someone and "trying to make them feel safe." In this definition, communication is fundamentally a process of confirming context and safety. P3 noted that the most important signals are often the simplest, "it could be safety, or danger rather, it could be hot or cold," and that exactly these signals "can kind of get lost in text."

Against this definition, the apps forced communication "to happen in a way that's more unnatural." In person or even on a video call, P3 explained, the environment forces people to respond to real stimuli, whereas the apps reduce a person to a curated set of photos and brief text. For LGBTQ+ users, this reduction has a specific cost. It removes the physical and emotional cues they rely on to filter whether someone is a safe person. The visual-centric medium therefore does not merely

fail to convey personality. It fails to support the safety assessment that, for our participants, precedes any genuine connection.

5.2.3 Photo-driven attention and performativity

The architecture also shaped how other users behaved toward participants. People paid attention and sent likes based on photos alone, regardless of the sexual or relationship orientations stated in a profile, and regardless of how much detail the profile owner had written. P2 captured the pattern from both sides: incoming likes felt like "they're just clicking on any picture that they find attractive... without bothering to look any deeper than just the pictures," and "it just seems like you didn't bother to read my actual profile, or maybe they saw one picture and were like, let me shoot my shot." P3 named the overall mode of self-presentation this produces: "there's also a level of performativity." On a visual-centric platform, profiles are oriented toward being looked at rather than being known.

5.3 Emotional Impact: Frustration, Threatened Safety, and Self-Doubt

5.3.1 Frustration and skepticism rooted in identity

All participants were frequently dissatisfied and frustrated by other users' behavior, and they located the cause in the app's structural limits on interpersonal discovery. Their reactions to mechanical, photo-only likes went beyond simple annoyance into strong aversion, confusion, and disappointment, and these reactions were tied to their identities.

For our participants, profiles functioned as a filter for finding identity-aligned people precisely because profiles allow them to state their sexual identity, relationship orientation (such as seeking a long-term relationship, or no-kiss boundaries), and political orientation, which they explicitly connected to their safety and alignment, alongside their personality. When other users ignored this information, the neglect read as more than laziness. P2 felt disappointed and confused when likes arrived from people who clearly had not read these descriptions, because ignoring them signaled a lack of respect for P2's identity and stated relationship boundaries, which in turn harmed their sense of safety. The same concern sharpened into feeling objectified when P2 encountered profiles advertising themselves with "no condoms" and photos that sexually objectified women: "they put like what would win them over is no condoms, and I was like, that is really gross to me." These encounters directly opposed P2's sexual identity, and the intensity of the reaction traced back to a fundamental, ongoing vigilance about hostility: "I'm very aware of being seen safe and just worried about whether someone's going to not be okay with my identity and whether they're going to be hostile towards that, or disrespectful... I'd rather err on the side of caution." For P2, every careless or aggressive signal on the app was processed through this hyperawareness.

P1 similarly "just didn't really feel great" about being liked without context, and P3 expressed extreme annoyance and frustration at the majority of profiles with unfulfilled bios, a frustration intensified by the asymmetry of effort. P3 had written extensive personal information into their own bio precisely because they prioritized personality. P3 went as far as naming these empty profiles "nothing burgers," burgers with no bun and no patty. These reactions are best understood through participants' initial motivation. They needed personal context and information to build genuine relationships, and the surrounding user population, shaped by the same visual-centric architecture, was not prioritizing that at all.

P3's frustration also carried a minority-specific realization. Reflecting on the limits of connection on the apps, P3 invoked a saying from the Black community, "not all skinfolk are kinfolk." Sharing Black queer identity, or a common interest like being a Swiftie, did not guarantee emotional resonance, and without that resonance genuine connection was impossible. For a minoritized user navigating an already small dating pool, discovering that apparent in-group matches still lacked emotional fit was a bitter lesson the visual-centric filter could neither predict nor prevent.

5.3.2 Restricted self-expression and the burden on body image

The photo-centered structure also restricted the natural ways they could express their own personality, which made the apps feel more distant. This burden fell unevenly. For P1, who had transitioned relatively recently and rarely took photos, the photo requirement approached structural exclusion: "I don't have a huge amount of photos that I can show of myself in the presentation that I like, and that I think looks good. And the issue with dating apps as a concept is that it relies a lot on having photos of yourself that you can show off... and if I just don't have those, then dating apps as a concept are just not going to work for me." A design choice that is merely inconvenient for users with years of comfortable photos becomes a barrier to entry for a trans user whose visual self-archive does not yet match their identity.

The visual economy also affected participants' confidence and self-validation to how they were perceived visually by strangers. Receiving compliments and many likes increased their self-confidence, while a lack of reaction discouraged them. The same economy fueled body comparison regardless of participants' actual preferences. Confronted with a toned body, P3 reported pressure and "maybe inferiority is the right word here," concluding "this ain't won't be a match" before noting the irony, "the toned body isn't even my preferred body preference." The comparison was imposed by the medium, not chosen by the user.

5.3.3 Stalled conversations and self-doubt about social skill

These traits carried into the next stage of engagement, conversation. The lack of interpersonal cues beyond body images often restricted participants' ability to initiate conversation at all, producing anxiety, awkwardness, and self-doubt about their social skills. P1 connected the problem directly to their values, "I tend to value a person's personality over anything else, so if I

am struggling to get a sense of what their personality is, then it's hard to know what I should do." When attempts stalled, participants interpreted low-context silence as personal failure. P2 concluded "I feel like I'm really bad at conversations" after receiving no response, and described ice-breaking as "really awkward... especially if it doesn't feel like they're reciprocating a ton." P3 replayed an unanswered greeting in search of a mistake that did not exist: "I felt like in that moment I had done something wrong, or like I came off as weird or creepy... what I did was say hi. I really don't know."

5.3.4 Self-doubt about one's core values

Beyond social skill, the accumulated mismatches led participants to question their core values and standards themselves. P2 grew "more jaded with the dating app experience," asking "it isn't what the majority of people on here are doing. Is it even worth it to keep going?" P3 began second-guessing their own interpretations mid-reflection, wondering whether they were projecting and going "too deep into the weeds." P1 needed external confirmation before trusting their own judgment: having friends agree that an empty profile "means nothing" was what "made me feel like I wasn't just being too picky, and that, no, there really is nothing here." The uncertainty that originated in the interface was being metabolized as doubt about the self.

5.4 Coping Behaviors: Protecting Core Values and Seeking Validation

Participants did not absorb these effects passively. Their coping behaviors reveal both how they protected themselves and what they actually wanted from the medium.

The first strategy was a deliberate messaging practice that resisted the visual economy. P2 felt nothing when others sent photo-only signals, and so refused to reproduce the pattern in their own outreach. Instead of commenting on appearance, P2 consistently asked about the human interests and context visible in photos: a cosplay character (Day 3), the location of a garden in a photo, which turned out to be the Amazon Spheres (Days 3 and 4), and a filmmaking project (Day 7). This curiosity-driven practice was not incidental. It was an active behavior to preserve their core value of personality prioritization inside an environment that structurally discouraged it.

The second strategy was asking friends for validation. P2 shared bad or confusing app and dating experiences with friends to confirm that their own reactions made sense. P1 likewise relied on friends to verify that a barren profile really contained nothing, and that the problem was the profile rather than P1's pickiness. In both cases, friends served as an external reality check that restored confidence the apps had eroded.

5.5 Cumulative Self-Questioning Produces Emotional Fatigue

When this cycle repeated across the diary week, it drained participants in recognizable stages. For some, the experience registered as stress and burnout. P2 concluded the app had become "more stress than it was worth," and P1 described the dominant feeling during use as fatigue. App use was not a casual pastime. It demanded ongoing emotional energy while returning little.

For others, fatigue appeared as a quieter loss of hope. P1 described opening the app each day with "lesser and lesser expectations" that anything meaningful would come of it. The app did not destroy participants' self-worth outright, but it steadily eroded their belief that the platform could deliver the connection that motivated them in the first place.

At the far end of this trajectory, fatigue settled into detached indifference. P1 called the experience mind-numbing, and P3 described opening the apps absentmindedly, "window shopping" through profiles without intent. At this point the app had inverted its purpose. A tool downloaded in pursuit of genuine connection had become a repetitive, emotionally distant routine.

5.6 Motivation Changes: Lowered Expectations and Guarded Re-engagement

The emotional impact of the apps was a slow fatigue. The platform kept asking users to invest effort while giving little meaningful return, and once the apps became emotionally tiring, participants changed how they engaged. One response was stepping away entirely when the app became more stressful than worthwhile. And when participants came back, they returned with stronger boundaries and more skepticism about how much of themselves to invest.

These behaviors shaped the next phase of motivation, closing the loop with which the findings began. Participants remained open to connection. Their foundational desire for genuine, identity-aligned relationships did not disappear. But each cycle of engagement left them more guarded about the effort they were willing to spend, lowering the expectations they carried into the next session.

6 Impact of Findings

Our findings carry implications for two distinct audiences: the people who build dating apps, and the people who use them.

For product teams and UX designers, the central takeaway is that many of the negative experiences our participants described were shaped by the design of the apps themselves, especially shallow profiles and repetitive, low-reward interactions. These findings can be used to

push dating app companies to reduce the interaction patterns that contribute to emotional fatigue, and more importantly, to design for sustainable and rewarding experiences rather than short-term engagement. Concretely, that means building features that give personality more structural weight: richer ways to express interests and context, profile formats that reward depth over photo volume, and interaction mechanics that encourage curiosity about a person rather than rapid visual evaluation.

For the LGBTQ+ community, we hope these findings serve as validation. Across our study, participants described frustration, awkwardness, pressure around self-presentation, and emotional fatigue as recurring parts of app use. Knowing that these experiences are common, and that they are at least partly products of design rather than personal failure, can help queer users approach dating apps with more realistic expectations instead of blaming themselves when the experience feels shallow or draining. The findings also point toward healthier patterns of use: setting boundaries, taking breaks, muting notifications, or stepping back entirely when app use begins to affect mental well-being. In that sense, this study does not only describe problems. It can help users recognize warning signs early and protect themselves emotionally.

Dating apps are here to stay in modern dating. Our hope is that these findings contribute to making them healthier and more supportive places to build meaningful connections.

7 Future Work and Reflection

7.1 Future Work

The queer community is itself highly diverse, and our findings should be read as a starting point rather than a complete picture. If time had allowed, we would have focused on specific subcommunities, such as trans or asexual users, whose relationships to a visual-centric, orientation-tagged platform may differ in important ways. For the broader research community, we suggest longitudinal studies that track users across multiple cycles of engagement and withdrawal, and comparative work examining how gender identity, sexual orientation, and race intersect with app experience. For designers, we suggest prototyping and testing personality-first features with queer users directly, evaluating their impact on emotional outcomes alongside engagement metrics.

7.2 Reflection: What We Would Do Differently

If we were to repeat this study, we would make several adjustments. First, we would run a longer diary study, since a single week limited how much of the fatigue trajectory we could observe, and some participants did not complete entries every day. Second, we would diversify the diary format, varying prompts across days or inviting participants to submit images, memes, or short

videos, both to keep participants engaged and to capture experience through more than one medium. Third, we would recruit more participants to support stronger thematic saturation and cross-participant comparison.

7.3 Limitations

Our findings rest on a small sample of four participants, which is appropriate for exploratory qualitative work but limits generalizability. Participant dropout also constrained our analysis, as one participant withdrew before the interview phase, leaving diary data without contextual depth. In addition, although the participants in this study did not exhibit pronounced, identity-driven differences in their sensemaking processes, as universal human experiences predominantly characterized the data, this may reflect a limitation of the current sample size or demographic scope rather than a true absence of such differences. Future research warrants a more granular investigation into the subtle ways specific identities might exert localized influence on how users interpret and respond to dating app experiences.

8 AI Statement

We used AI as a supplementary tool in three parts of this project: consent form drafting, analysis and report writing.

In creating the consent form, we outlined the risks and benefits for the study and used AI to generate a polished consent form we could send out.

In our analysis, we used FigJam's AI-assisted card sorting feature during the affinity diagramming process to produce an initial topic-based grouping of codes. The research team then manually reviewed each grouping against its original context, reclassified codes where needed, and identified themes. All key findings were derived by the team without the use of AI.

For the final report, team members first wrote freewriting drafts and outlined the structure and direction of each section. AI was then used to compose a polished draft based on these materials, along with our presentation script and other existing deliverables. The team reviewed, revised, and finalized all content.

9 Appendix

9.1 Recruitment Artifacts

9.1.1 Recruitment post

Hi! 👋

We're a team of UW HCDE students conducting a research study to better understand the experience of the LGBTQ+ community on dating apps. If you're interested in participating in our study, please fill out the form below: https://forms.gle/NUxjo4a6utP9assY8

9.1.2 Screening survey

https://forms.gle/xLbDq9awAgCBcjEs7

9.1.3 Participant pool table

P#	Age	Gender Identity	Sexual Orientation	App Usage	Primary Intention	Study Status
P1	18-24	Transgender woman	Questioning / Unsure	Daily	Long-term relationship	Full Study
P2	18-24	Transgender woman	Bisexual	Once a week	Curiosity / Exploring	Full Study
P3	18-24	Man	Gay or Lesbian	Daily	Unsure	Full Study
P4	25-29	Non-binary	Gay or Lesbian	Several times/week	Long-term relationship	Diary only
